 TITLE: Numerical method for finding asymptotically stable solutions to a system of ordinary differential equations
 SOURCE: AN SSSR. Doklady, v. 167, no. 4, 1966, 739-742
 TOPIC TAGS: ordinary differential equation, asymptotic property, numeric analysis
 ABSTRACT: Asymptotically stable solutions are searched for the system of ordinary differential equations given by

$$dx/dt = f(t, x) \quad (f = (f_i)_{i=1}^n, \quad x = (x_i)_{i=1}^n). \quad (1)$$
 The goal is to find the algorithm for the asymptotically stable solution in the domain G, or

$$x^0(t) \quad (\|x^0(t)\|^2 = \sum_{i=1}^n |x_i^0(t)|^2 < M). \quad (2)$$
 The proof is carried out by showing that a Lyapunov function $F(t, x)$ exists for the above system with the following properties: a) a continuous function $W_1(x)$ exists such that

$$W_2(x) \geq V(t, x) \geq W_1(x), \quad \text{where } W_2(x^0(t)) = 0, W_1(x) > 0 \text{ at } x \neq x^0(t). \quad (3)$$
 Card 1/2 UDC: 518.517.91/94

ACC NR: AF6011422

0

and $W_1(x) \rightarrow \infty$ at $x \rightarrow \partial G$; b)

$$dV(t, x)/dt = \partial V/\partial t + (\text{grad}_x V, f(t, x)) < -W_2(x) < 0 \text{ at } x \in \bar{G} \setminus x^0; \quad (4)$$

and c) the function $V(t, x)$ has continuous partial derivatives in all the arguments uniformly bounded in t on each $H \subset G$. It is then proved by means of several theorems and lemmas that: a) if x^0 is asymptotically stable in all space of equation (1), then for any sequence

$$\{(A_n)_{n=1}^\infty, (S_n)_{n=1}^\infty, (a_n)_{n=1}^\infty\} \text{ where } (A_n)_{n=1}^\infty \text{ at } n \rightarrow \infty, (S_n)_{n=1}^\infty \text{ and } (a_n)_{n=1}^\infty (a_n \rightarrow 0 \text{ at } n \rightarrow \infty, \sum_{n=1}^\infty a_n = \infty) \quad (5)$$

and for any initial point x_0 the algorithm

$$\mathcal{A}_1((A_n)_{n=1}^\infty; (S_n)_{n=1}^\infty; (a_n)_{n=1}^\infty) \quad (6)$$

stabilizes at some stage j_0 and generates the sequence $\{x_n(j_0)\}_{n=0}^\infty$ converging to x^0 ;

b) if x^0 is asymptotically stable in the uniformly bound domain

$$H_1 = \{x: \Phi(t, x) \leq c\} \quad (7)$$

in t , such that $\Phi(t, x) = c$, then for any initial point $x_0 \in H_0$ and the sequence

$$\{(S_n)_{n=1}^\infty, (a_n)_{n=1}^\infty (a_n \rightarrow 0, \sum_{n=1}^\infty a_n = \infty)\}, \quad (8)$$

the algorithm

$$\mathcal{A}_2(\Phi; (S_n)_{n=1}^\infty; (a_n)_{n=1}^\infty) \quad (9)$$

stabilizes at some stage j_0 and generates the sequence $\{x_n(j_0)\}_{n=0}^\infty$ converging to x^0 .

TITLE: Transformation operator for Sturm-Liouville differential equations in the non-self-adjoint case

PERIODICAL: Akademiya nauk SSSR. Doklady, v. 142, no. 5, 1962, 1019-1021

TEXT: The author investigates transformation operators $V[LL_1hh_1]$ which transform the solution $\omega_h(x, \lambda)$ of the boundary value problem $L[u] + \lambda^2 u = u'' - q(x) + \lambda^2 u = 0, u'(0) = h, u(0) = 1$ into the solution $\omega_{h_1}(x, \lambda)$ of the boundary value problem $L_1[y] + \lambda^2 y = y'' - q_1(x)y + \lambda^2 y = 0, y'(0) = h_1, y(0) = 1$. Such operators can be represented in the form

$$V[f] = f(x) + \int_0^x H(x, t)f(t)dt.$$

Card 1/2

Transformation operator for ...

S/020/62/142/005/008/022

delta function

ABSTRACT: A linear dynamical system subjected to shocks and described by the equation

$$\frac{d\xi}{dt} = A\xi + \sum_{t_i < t} \Delta_i \xi \cdot \delta(t - t_i), \quad \xi(t_0) = \xi^0.$$

Card 1/3

L 20071-65

ACCESSION NR: AT4049211

is considered, where the $\Delta_i \xi$ ($i=1, 2, \dots$) are finite sudden variations in the solutions at the time t_i and δ is a delta function. The problem of boundedness of the solution of this equation was studied and the corresponding estimates were given on the assumption of an a priori estimate of the amplitude of shocks $\Delta_i \xi$ in a previous article by V.D. Mil'man and A.D. Myshkis (On the stability of motion in the presence of shocks. Sib. mat. zh-1, vol. 1, no. 2, 1960, 233-237). The aim of this article is to carry out a probabilistic study of the behaviour of the trajectories of the system under the assumption that the shocks do not occur too frequently, their amplitudes are not, in general, small, and the solutions

$$\frac{d\xi}{dt} = A\xi$$

are asymptotically stable. The concepts of weak convergence and strong convergence were introduced for the comparison of weak trajectories.

TITLE: Alkylation of toluene with the propane-propylene fraction of catalytic cracking gas

PERIODICAL: Referativnyy zhurnal. Khimiya, no. 13, 1962, 534, abstract 13M216 (Novosti nef. i gaz. tekhn. Neftepererabotka i neftekhimiya, no. 10, 1961, 7-10)

TEXT: Experiments on the alkylation of coal-tar toluene, using the propane-propylene fraction of catalytic cracking gas in the presence of dehydrated $AlCl_3$ as catalyst, were carried out at atmospheric pressure in a laboratory apparatus in order to determine the ideal yield of the alkylate produced, and its anti-detonation properties. It was established that the ideal conditions for formation of the required 120-180°C fraction are: temperature 75°C, toluene: propylene: $AlCl_3$ molecular ratio

1:0.5:0.035, contact period 0.64 min. Under these conditions the yield of the fraction was: 206.3 % with respect to propylene, 106.4 % with respect

Card 1/2

Theory of electrical resistivity of ordered alloys. A. K. Butylenko, V. M. Danilenko, Yu. V. Mil'man, Yu. V. Naldich, S. A. Rybak, and A. A. Smirnov. *Izv. Akad. Nauk. Politekh. Inst.* 12, 18-24 (1953); *Referat. Zhur., Fiz.* 1955, No. 9374; cf. *C.A.* 47, 3644e.—Exptl. curves illustrating the relation of elec. resistivity of ordered alloys ρ to compn. and degree of ordering differ from theoretical curves by the presence of rectilinear sections, by sharpness of the max., and in some cases by the rapid discontinuous changes of ρ with compn. If one considers that, at the same temp. for annealing T , the degree of ordering η , attained by alloys of different concns., is not the same, then the exptl. curves can be explained with the aid of known formulas detg. the equil. values of η at given values of T and c (conc.). The favorable effect of the indicated correction is illustrated graphically by a sample of alloys with face-centered and body-centered cubic lattices. It is noted that the skipping of $\rho(c)$ which is sometimes observed when compn. $c = 0.5$ is approached contradicts the statistical theory of ordering, which is not able to predict whether the order—non-order transitions in a given alloy are of 1st or 2nd order. This work confirms the usefulness of A. A. Smirnov's theory (*C.A.* 42, 8005f) in explaining the basic qual. features of change in ρ with the compn. which are observed in ordered alloys. M. K.

TEXT: The authors apply a mathematical treatment of dislocation theory to calculate the brittle transition temperature T_x for low-carbon steel and cast molybdenum. Their results agree well with experimental results for both materials. However, for considerably smaller block sizes calculated results are low. An increase in the speed of deformation from 10^{-4}sec^{-1} to 10^2sec^{-1} causes T_x to rise, the absolute increase (which can exceed 200°C) being much greater for molybdenum than for iron. This explains the profound effect of test conditions on the T_x values for molybdenum and the fact that its notch sensitivity is higher than that of steel. A decrease in grain size reduces T_x more in molybdenum than in steel; decrease in substructure size and

Card 1/2

Contribution on the brittle ...

S/601/62/000/016/002/029

increase in dislocation density reduces T_x for both materials.
It is confirmed that by varying the substructure it should be
possible to vary the transition temperature over a wide range.
There are 2 figures and 2 tables.

TITLE: The electromechanical effect in covalent crystals as a function of temperature 21

SOURCE: AN UkrSSR. Institut metallofiziki. Sbornik nauchnykh trudov, no. 19, 1964. Voprosy fiziki metallov i metallovedeniya (Problems in the physics of metals and physical metallurgy), 51-53

TOPIC TAGS: indium antimonide, silicon, germanium, electromechanical effect, semiconductor 21 27 27 21 27

ABSTRACT: The electromechanical effect discovered by Westbrook and Gilman consists of a sharp drop in the microhardness of several crystals with covalent bonds (Si, Ge, InSb, etc.) when an electric current is passed through the specimen during measurement. In many cases, this drop in hardness amounts to 50-60% independently of the conductivity type of the crystal (n- or p- type). The electromechanical effect increases with an increase in the current density j , but reaches saturation at some point, e.g. the saturation point for Ge is 100 a/m². This is a surface

Card 1/3

L 33335-65

ACCESSION NR: AT5005114

effect, acting only at distances of 2-3 μ from the surface. It has been established that passing a current through the specimen generates the same effects as are observed when it is illuminated by light of a definite wavelength. The authors of this article had previously studied the effect of temperature on the microhardness of Si, Ge and InSb in a wide temperature range as well as the movement of dislocations at various temperatures in these crystals. It was shown that below some temperature T_{cr} the hardness is weakly dependent on the temperature and that the dislocations are nearly stationary. When the temperature is raised above T_{cr} , the hardness falls sharply while the rate of motion of the dislocations increases. For all crystals studied, $T_{cr} = 0.4 T_m$ where T_m is the melting point in $^{\circ}K$. A comparison of these results with the data on the relationship between temperature and the electromechanical effect obtained by Westbrook and Gilman (J. H. Westbrook, J. J. Gilman, Journ. Appl. Phys., 1962, 33, 7, 2360) provided a basis for assuming that the electromechanical effect takes place only at temperatures below T_{cr} . In order to verify this hypothesis, the electromechanical effect in an InSb monocrystal was studied since its T_{cr} lies in the room temperature range and it lends itself most easily to testing above and below T_{cr} . The results are presented in graphic form. It is found that the electromechanical effect takes place only below T_{cr} , the effect being greater the lower the temperature. At temperatures above T_{cr} , where

Card 2/3

7 33335-65

ACCESSION NR: AT5005114

there is considerable dislocation mobility, there is no electromechanical effect. Thus this effect is observed in covalent crystals only when the dislocations in these crystals are "frozen." Orig. art. has: 3 figures. 14

TITLE: Investigation of the mechanism of deformation and brittle failure of transition-metal alloys on a VI A-group base

SOURCE: AN UkrSSR. Institut metallofiziki. Sbornik nauchnykh trudov, no. 20, 1964. Voprosy fiziki metallov i metallovedeniya (Problems in the physics of metals and physical metallurgy), 3-24

(Problems in the physics of metals and physical metallurgy), 3-24

TOPIC TAGS: chromium alloy, iron containing alloy, tungsten alloy, rhodium containing alloy, nil ductility temperature, brittle failure mechanism, slip mechanism, twinning mechanism

ABSTRACT: The mechanism of the action of alloying elements on the cold brittleness temperature of alloys and the role of twinning in the observed decrease in the NDT temperature have been investigated in 99.998% pure chromium and chromium alloys containing up to 53.2 at% Fe and in pure tungsten and tungsten alloys containing 10 and 25 at% Re. The temperature dependence of the yield strength and hardness measurements at tem-

of the alloys was determined by microhardness

peratures ranging from -253 to +800C. The cold brittleness and the plastic deformation with slip and with twinning were investigated with static bend tests. When the temperature of the beginning of twinning at which the plastic deformation mechanism experiences the slip-to-twinning transition (T_d) is higher than the NDT temperature, the latter decreases sharply with a further increase in the iron content of the alloys. Similarly, in W-Re and Mo-Re alloys, an addition of rhenium raises the T_d and lowers the NDT temperature in the twinning region, changing significantly the plastic deformation mechanism. In all the investigated alloys, a wider temperature range of cold brittleness is observed at higher NDT temperatures and vice versa. This is probably because at low NDT temperatures the brittleness appears in the region where the yield strength is highly temperature-dependent, whereas at high NDT temperatures the temperature dependence of the yield strength is very slight. This phenomenon seems to be common for the b.c.c. lattice of refractory metals.

TITLE: Ductility of chromium alloyed with yttrium

SOURCE: AN UkrSSR, Institut metallofiziki. Sbornik nauchnykh
trudov, no. 20, 1964. Voprosy fiziki metallov i metallovedeniya
(Problems in the physics of metals and physical metallurgy), 25-31/

TOPIC TAGS: chromium, chromium alloy, yttrium alloy, microhardness,
alloy microstructure, alloy ductility, alloy strength, plastic
deformation effect

ABSTRACT: The effect of yttrium additions of 0.5, 1.0, or 2.0% on the ductility of 0.02%-pure electrolytic chromium has been investigated. Yttrium additions, particularly 0.5—1.0%, appreciably decreased the hot microhardness of alloys in the as-cast condition and raised the NDT temperature in static bend tests from -30C for pure chromium to -10C for an alloy with 1% Y. Microscopic examination showed a network of precipitated impurities along the grain boundaries

Card

of alloyed chromium which caused an increase in NDT temperature, notwithstanding a decrease in hardness. Hot extrusion with a reduction of 92% fragmented the precipitation network, and subsequent

with Cr-Y to -20 to -30C. Additional plastic deformation (drawing or rolling) at temperatures below the recrystallization temperature lowered the NDT temperature still further. The lowering of the NDT temperature can be ascribed to changes in the structure manifested by a substantial elongation of the grains, to changes in the substructure manifested by a significant strengthening of the deformed metal, and to the development of deformation aging processes. Thus, cold plastic deformation (below the recrystallization temperature) substantially lowered the NDT temperature of Cr-Y alloys and simultaneously increased their strength. ABSTRACT: The paper is a continuation of a previous work (Mil'man, Yu. V., Trefilov, V. I., Rachek, A. P., "Problems in the Physics and Science of Metals, 20", *Naukova dumka*, Kiev, 1964) devoted to the mechanism of plastic deformation and brittle fracture of alloys of elements in group VIA with other transition metals. The following alloy systems are studied: Cr-Mn, Cr-Ru, Cr-Fe, Cr-Os, W-Re, Mo-Re, Nb-Re and Mo-Ti. The alloys were studied in the cast state and in some cases were subjected to heat

18 treatment. The relationship between the packing flaw energy and the electronic structure of the alloy is analyzed. It is shown that both transition and nontransition metals conform to the Seger rule on high energies for packing defects in metals. The twinning \neq slipping transition in alloys of transition metals is studied. All alloys of elements in group VIA with metals in groups VIIA and VIIIA show a transition to twinning, while alloys with elements in group VIA (Mo-Ti alloys) show no twinning throughout the entire region of solid solutions with a bcc lattice under maximum loads. Experimental data show that alloying chromium, molybdenum and tungsten with metals of groups VIIA and VIII reduces the packing flaw energy and causes a transition to deformation by twinning (or to combined deformation by slipping and twinning). A brief survey of the literature shows no transition to twinning in alloys of group VIA with transition metals to the left of the chromium group in the periodic table. Orig. art. has: 8 figures.

TITLE: Investigation of the effect of highly active elements on the plasticity of chromium 16 27

SOURCE: AN UkrSSR. Fizicheskaya priroda khrupkogo razrusheniya metallov (Physical nature of brittle failure of metals). Kiev, Izd-vo Naukova dumka, 1965, 101-111

TOPIC TAGS: chromium, plasticity, metal aging, yttrium, rare earth element

ABSTRACT: The article deals with the refining of chromium by treatment with highly active elements which react with the interstitial impurities in Cr to form more stable compounds than the corresponding Cr compounds. To this end, the use of Y and other rare-earth elements is particularly promising since then it is often possible to improve not only the plasticity but also the high temperature strength of the alloy. However, there is no common consensus on this effect of Y and rare-earth elements. Thus, O. N. Carlson et al. (Less Common Metals, 1964, 6, 6, 439) present experimental findings indicating that the temperature of cold brittle-

Cord 1/3

I. 11026-66

ACC NR: AT6009600

ness of cast Cr increases when it is treated with Y and other rare-earth elements. To clear up this contradiction, specimens of Cr treated with Y as well as of pure Cr in soldered and evacuated ampoules were annealed at 1200°C for 1 hr and water-quenched. By means of Vickers hardness tests, aging of these specimens was investigated at three temperatures (275°, 350° and 400°C) in a molten-tin bath. The findings on the increase in microhardness with aging are presented in Fig. 1, where each point represents the mean of 8-10 measurements. Fig. 1

Fig. 1. Effect of treatment with Y and Pr on the aging of Cr:

○ - zone-refined Cr; ● - alloy of Cr + 1% Y; △ - alloy of Cr + 1% Pr

Card 2/3

L 141026-66

ACC NR: AT6009600

indicates that the addition of Y virtually suppresses the processes of aging in the alloy (and hence also it suppresses the rise in the temperature of cold brittleness due to the segregation of an interstitial impurity -- nitrogen -- from the solid solution). These findings confirm the feasibility of using Y to improve the refining of Cr, since Y binds the greater part of nitrogen into nitrides, thus suppressing most of the effects of aging. Further tests, involving the treatment of Cr with microamounts of Y and Pr over a broad temperature range: from the temperature of liquid hydrogen to +900°C, showed that such treatment enhances the microhardness of Cr at elevated temperatures. TITLE: The effect of annealing temperature on Q^{-1} and G-purity chromium and alloys of chromium with yttrium and gadolinium

SOURCE: AN SSSR. Institut metallurgii. Vnutrenneye treniye v metallakh i splavakh (Internal friction in metals and alloys). Moscow, Izd-vo Nauka, 1966, 56-62

TOPIC TAGS: internal friction, annealing, temperature dependence, chromium, high purity metal, yttrium, gadolinium, metallographic examination, grain structure, dislocation effect

ABSTRACT: The effect of annealing temperature on temperature dependent internal friction was studied in zone melted chromium, Cr + 1% Y, and Cr + 1% Gd. Wire samples of 0.8 mm diameter were drawn at 300°C to about 95%. These wires were annealed before testing for 1 hr at temperatures ranging from 100 to 1100°C. At low testing temperatures the internal friction in the pure chromium was twice as low as that in the alloys. In all cases, the internal friction decreased as a function of annealing temperature; in zone refined chromium, the internal friction dropped from $15 \cdot 10^{-4}$ to $5 \cdot 10^{-4}$ after annealing to 300°C; in Cr + 1% Y, the internal friction decreased at 50°C after

Card 1/3

L 04183-67

ACC NR: AT6026909

annealing up to 600°C. These changes were partially caused by the redistribution of interstitial impurities during annealing. Transmission electron microscopy showed that the density and distribution of dislocations did not change after annealing up to 400°C. Thus in the alloys the internal friction decrease was caused by polygonization. Microstructures did not show any differences between pure chromium and the alloys that would account for the internal friction recovery. At high testing temperatures, the internal friction increased sharply due to grain boundary relaxation. The rise in internal friction at high temperatures was the same for all of the metals. The shift in initial rise of internal friction with annealing was caused by a decrease in both dislocation density and grain boundary area. After annealing at similar temperatures, the value of internal friction was highest in the alloys, due to the retardation of recrystallization by alloying. In the 300-600°C temperature range, the change in Q^{-1} was caused by polygonization in Cr + 1% Y (the recrystallization temperature of Cr-Y is above 800°C), while in pure chromium above 600°C it was due to recrystallization. Internal friction peaks occurred at 900°C in pure chromium at an oscillation frequency of 2.8 cps. In Cr + 1% Gd a similar grain boundary peak occurred at 960-970°C at a frequency of 2.1 cps. In Cr + 1% Y the peak was not observed because alloying with yttrium raised the peak into a higher temperature range. The temperature dependence of the square of the frequency is proportional to the shear modulus. Deviations from linearity were observed in the same temperature range where the sharp rise in Q^{-1} was observed. This change in shear modulus was caused by grain boundary relaxation and lat-

TITLE: The Curie Point in Thin Ferromagnetic Films (Tochka Kyuri v tonkikh plenkach ferromagnetikov)

PERIODICAL: Uch. zap. Khar'kovsk. un-t, 1955, Vol 64, pp 159-165

ABSTRACT: The Curie point θ was determined on Ni films (F) $1.17 \cdot 10^{-6}$ to $6.95 \cdot 10^{-6}$ cm thick and 2.7×2 cm² in area, applied onto glass by volatilization under vacuum, by measuring the relative variation of the magnetic moment of the F in a constant magnetic field upon an increase in temperature on a special instrument. In spite of the fact that the points obtained experimentally do not lie on the theoretical curve obtained by Klein and Smith (Klein and Smith, Phys. Rev., 1951, Nr 81, pp 378-380), $I_s/I_0 = f(T/\theta)$, where I_s is the intensity of the technical saturation magnetization, I_0 is the true magnetization, θ in thin F is lower than in thick ones; the decrease of θ becomes noticeable at $3 \cdot 10^{-6}$ cm thicknesses and less.

Title : Magnetic Properties of Magnetite at Low Temperatures

Orig Pub : Fiz. metallov i metallovedeniye, 1956, 3, No 1, 186-188

Abstract : A study was made of the effect of the temperature, at which the magnetic field (H) is turned on during the cooling of magnetite, on the temperature of the $\beta \rightarrow \alpha$ transition, and on the value of the magnetization intensity that occurs upon this change. It is observed that turning H on at temperatures above 120° K gives the same result (the magnetization increases by 10%). Different results, but results that are in agreement with each other, are obtained by turning H on at temperature below

Title : The Curie Point in Thin Films of Ferromagnetics

Orig Pub : Uch. zap. kharkovsk. un-t, 1956, 64, 159-165

Abstract : An experimental verification is made of the dependence of the Curie point on the thickness of the nickel films, obtained by the method of spin waves, i.e., the dependence $I_s/I_0 = f(T/\phi)$ is measured. Films are obtained by evaporation in vacuum on glass from a nickel wire or from a crucible made of aluminum oxide. The film area in all measurements was 27 x 2 cm, and the thickness was measured by the Sinel'nikov and Rapp method. The Curie point was measured from the relative change in the magnetic moment of the film upon increase in temperature. It was established

Card : 1/2

USSR / Magnetism. Ferromagnetism

F - 4

Abs Jour : Ref Zhur - Fizika, No 4, 1957, No 9509

Abstract : that the Curie temperature is independent whether the nickel is coated on cold or hot glass. The irreversibility of the first magnetization curve, its dependence on the speed of heating, and the increase in the magnetic moment at room temperature for nickel films coated on cold glass leads to the conclusion that apparently these films are in an unstable phase. It is found that as the thickness of the nickel films is reduced from 6.95×10^{-6} to 1.17×10^{-6} cm, the value of the Curie temperature diminishes from 360 to 134°. It is shown that even though the experimental points obtained do not fit the theoretical curve of Klein and Smith, the Curie point in thin nickel films is considerably reduced with diminishing thickness of the film, starting with 3×10^{-6} cm and below.

PERIODICAL: Uch. zap. Khar'kovsk. un-t, 1958, Vol 98, Tr. fiz. otd. fiz.-matem. fak., Vol 7, pp 275 - 279

ABSTRACT: In order to obtain additional information concerning the magnetic structure of Fe-Ni-Al alloys and the mechanism of their magnetization, the authors studied the initial slope of the magnetization curve of AlNi-3 alloys in fields from 0 to 200 oersteds. They measured the differential and reversible susceptibilities, which made it possible to clarify the boundary between the reversible portion of the magnetization curve and the beginning of its irreversible portion. Measurements were carried out on an astatic magnetometer. It is demonstrated that reversible magnetization processes extend up to fields of an order of 100 oersteds.

TITLE: Magnetic Anomalies of Magnetite

PERIODICAL: Fizika metallov i metallovedeniye, 1959, Nr 6,
pp 832-836 (USSR)

ABSTRACT: Early work on magnetic properties of magnetite (Ref 1) showed that at 120°K there is a sudden decrease in magnetization, later found to coincide with sudden changes in other physical properties (Refs 2,3,4). The magnitude of the magnetization change depends on cooling conditions (Ref 7). Magnetic anisotropy changes with falling temperature (Ref 6). The object of the present work was to study the magnetic properties of magnetite at 75-100°K and the influence of change of sign of magnetic-anisotropy constants above the transition temperature on magnetic properties at lower temperatures. A natural rhombohedral magnetite single crystal and a magnetometer of the type described by Domenicali (Refs 7,8) were used. The whole swinging part of the magnetometer was kept in a vacuum (10^{-1} mm Hg) to avoid convection currents. The

Card 1/3 specimen whose axis coincided with the coil axis was

Magnetic Anomalies of Magnetite

SOV/126-7-6-4/24

cooled from room temperature to 75°K in an external field of about 400 oersted: Fig 2 shows curves of magnetization against temperature for various cooling conditions. Similar results but with less change in magnetization were obtained with the $[111]$ axis along the coil axis. The authors give a graphical representation (Fig 3) of changes in magnetization with field commutation, which also applies to brief switching off of the field. In the previous work A. S. Mil'ner et al. (Ref 9) had dealt with the effect of temperature of application of the magnetic field on the value of the magnetization change, but with specimens with unknown crystallographic direction. In the present work the field was directed along the $[100]$ or $[111]$ directions, giving more regular results. Fig 4 shows plots of magnetization against temperature for $[100]$ directed field applied at 290, 95, 90 and 85°K. The transition of the magnetite through the null value of the anisotropy constant had no effect on these phenomena (in contrast to what occurred when the field was commutated at 75°K for specimens cooled in a field). The authors explain the effect of the temperature of application of the field on

Card 2/3

TITLE: Temperature dependence of magnetization of manganese ferrite in weak fields

PERIODICAL: Akademiya nauk SSSR. Izvestiya. Seriya fizicheskaya, v. 25, no. 12, 1961, 1437-1438

TEXT: For the purpose of comparing the processes in manganese ferrites with those in magnetite and cobalt ferrite, the temperature dependence of the magnetization of monocrystalline manganese ferrite between nitrogen and room temperature was measured with the use of a pendulum magnetometer in the following three cases: (1) Precooling the ferrite without magnetic field and raising the temperature from 80° to 280°K causes the magnetization to increase. (2) Precooling the ferrite in a magnetic field shows that magnetization at 80°K is higher than it is in the case mentioned under (1) and that it decreases steadily under heat action. (3) In case of precooling the ferrite in a field perpendicular to that applied during the magnetizing, magnetization shows the same behavior as in case (2).

Card 1/2

Temperature dependence of ...

31598
S/048/61/025/012/002/022
B125/B112

The values obtained at nitrogen and room temperature for the induction of a manganese ferrite by means of the ballistic method in a field of Helmholtz coils after cooling without field or after cooling in a field of 5 oe agree with results obtained by the magnetometer method. In (1) and (2) the temperature behaves under analogous conditions similar as in magnetite and cobalt ferrite, the magnetization of manganese ferrite does, however, change within a temperature interval considerable wider than that in the afore-mentioned cases. In the third case magnetization will always be increased by the field parallel or perpendicular to the magnetic field applied during the cooling. Contrary to this, the magnetization of magnetite and cobalt ferrite is diminished by applying a field. Hence the conversion of the energy spectrum of electrons in the low temperature range is more complex than that with magnetite. There are 1 figure and 10 references: 5 Soviet and 5 non-Soviet. The four most recent references to English-language publications read as follows: Domenicali C. A., Phys. Rev., 78, 459 (1950); Okamura, Simoizoka, Phys. Rev., 83, 664 (1951); Domenicali C. A., Rev. Scient. Instrum., 21, 327 (1950); Verwey E. et. al. J. Chem. Phys. 15, 181 (1947).

TITLE: Determination of the magnetic characteristics of thin ferromagnetic films

PERIODICAL: Pribery i tekhnika eksperimenta, no. 1, 1963,
131 - 132

TEXT: A torsion magnetometer is described for determination of magnetization curves and static hysteresis loops of ferromagnetic films in the temperature range 60 - 1 000 °K. The magnetometer is shown in Fig. 1. It consists of an evacuated glass or quartz tube 1. A quartz rod 4 is attached to a phosphor-bronze suspension at one end and to a copper holder 3 at the other. The film under investigation is placed in this holder, while the suspension 5 is attached to the copper rod 6 which passes through the glass-to-metal seal 7. A rigid copper frame 8 is firmly attached to the upper end of the quartz rod 4 with its plane perpendicular to the plane of the holder 3. The mirror 10 is attached to this frame and is used to observe the rotation of the system. One end of the frame is soldered onto the

lower end of the suspension 5 , while the other end of the frame is soldered to a copper wire which forms a thermocouple junction with a constantan wire 14 at the holder 3 . The other end of the constantan wire is taken up through the glass-to-metal seal, forming a spiral around the suspension 5 . The necessary temperature is produced by placing the lower part of the tube in an electrical heater or a dewar. Thus, two leads are sufficient to determine the magnetization of the film by passing a compensating current through the coil 8 , the temperature being measured by the thermocouple. Fig. 3 shows the hysteresis loop for 2 650 Å thick nickel film on a glass base. The experimental points are in satisfactory agreement with the theoretical curves. There are 3 figures.
